## Limit theorems for extrema due to Gnedenko (with complements due to de Haan)

- $\{X_j\}_{j \in \mathbb{N}}$  - an i.i.d. sequence of random variables,  
 $M_n = \max_{1 \leq j \leq n} X_j$ ,  $n \in \mathbb{N}$ .
- Problem: find  $a_n > 0$ ,  $b_n \in \mathbb{R}$  and a non-degenerate distribution function  $H$  such that

$$(*) \quad \lim_{n \rightarrow \infty} P((M_n - b_n)/a_n \leq x) = H(x), \quad x \in \mathbb{R}.$$

- Question I: identify possible types of limiting distributions (3 types or one-parameter family indexed with  $\gamma \in \mathbb{R}$ ).
- Question II: describe when a particular distribution  $F$  of  $X_j$  leads to the given limiting  $H$  (“domains of attraction”).
- Question III: for given  $F$  and  $H$  determine asymptotically  $a_n$  and  $b_n$ .
- Question IV: find a rate of convergence in (\*).

## Comments on the extreme value limit theory

- (+) Parallels the limit theory for sums.
- ( $\pm$ ) There exists a variety of limiting laws with quite different properties.
- (−) Limiting laws in general do not scale: if  $X_j$ 's are standard normal and

$$\lim_{n \rightarrow \infty} P((M_n - b_n)/a_n \leq x) = \exp(-e^{-x}),$$

and if  $X_j' \sim \mathcal{N}(0, \sigma^2)$ , where  $\sigma^2 \neq 1$ , then

$$\lim_{n \rightarrow \infty} P((M_n' - b_n)/a_n \leq x) = \text{either } 0 \text{ or } 1.$$

- (−) The last property makes difficult deducing limit properties on the base of conditional distributions.
- (−) In many practical tasks only a **single sequence**  $\{v_n\}$  is of interest. For example:
  - For given  $\alpha$  **close to 1** find

$$\lim_{n \rightarrow \infty} P(M_n \leq v_n) = \alpha \in (0, 1).$$

- Find exact asymptotics (large deviations) of

$$P(M_n \geq v_n) \rightarrow 0.$$

Bibliography

- Basic observation. If  $\{X_j\}$  are i.i.d. and  $X_j \sim F$ , then for **arbitrary** sequence  $\{v_n\}$

$$P(M_n \leq v_n) = F(v_n)^n = \exp(-n(1 - F(v_n))) + o(1).$$

- O'Brien's (1974) observation: Given  $\alpha \in (0, 1)$ , it is possible to find constants  $\{v_n = v_n(\alpha)\}$  such that

$$P(M_n \leq v_n) = F(v_n)^n \rightarrow \alpha, \text{ as } n \rightarrow \infty,$$

if, and only if,

$$F(F_*-) = 1 \quad \text{and} \quad \lim_{x \rightarrow F_*-} \frac{1 - F(x)}{1 - F(x-)} = 1,$$

where

$$F_* = \sup\{x : F(x) < 1\}.$$

- If for **some**  $\alpha \in (0, 1)$  then for **every**  $\alpha \in (0, 1)$ !

## O'Brien's theory for maxima of stationary sequences

- By definition, a distribution function  $G$  is **regular** (in the sense of O'Brien) if

$$G(G_*-) = 1 \quad \text{and} \quad \lim_{x \rightarrow G_*-} \frac{1 - G(x)}{1 - G(x-)} = 1.$$

- Now suppose that  $\{X_j\}$  is a **stationary sequence** of random variables, with marginal distribution  $F$ .
- Following O'Brien (1987) we call any distribution function  $G$  satisfying

$$(*) \quad P(M_n \leq v_n) - G^n(v_n) \rightarrow 0, \text{ as } n \rightarrow \infty,$$

for **all** sequences  $\{v_n\}$ , a **phantom distribution function** for  $\{X_j\}$ .

- Clearly  $(*)$  is equivalent to

$$\sup_v |P(M_n \leq v) - G^n(v)| \rightarrow 0, \text{ as } n \rightarrow \infty.$$

- $G$  is not uniquely determined!

## O'Brien's theory for maxima of stationary sequences

## O'Brien's theory for maxima of stationary sequences

### Theorem

Let  $\{X_j\}$  be stationary. The following are equivalent:

- 1 The sequence  $\{X_j\}$  admits a regular phantom distribution function.
- 2 There exists a sequence  $\{v_n\}$  and  $\alpha \in (0, 1)$  such that

$$P(M_n \leq v_n) \rightarrow \alpha.$$

and the following **Condition  $B_\infty(v_n)$**  holds: as  $n \rightarrow \infty$

$$\sup_{p,q \in \mathbb{N}} |P(M_{p+q} \leq v_n) - P(M_p \leq v_n)P(M_q \leq v_n)| \rightarrow 0,$$

- 3 There exists  $\alpha \in (0, 1)$  such that for some dense subset  $\mathbb{Q} \subset \mathbb{R}^+$

$$P(M_{[nt]} \leq v_n) \rightarrow \alpha^t, \quad t \in \mathbb{Q}.$$

Non-stationarity

Bibliography

- In fact, given  $\alpha \in (0, 1)$  and  $\{v_n\}$  we can **construct** a regular phantom distribution function  $G$  for  $\{X_j\}$ .
- First, we can replace  $\{v_n\}$  with

$$v_n^* = \begin{cases} \max\{v_k : 1 \leq k \leq n, v_k < F_*\} & \text{if } \neq \emptyset, \\ \inf\{v_n : n \in N\} & \text{otherwise,} \end{cases}$$

which is **nondecreasing**.

- Then one can define

$$G(x) = \begin{cases} 0, & \text{if } x < v_1^*, \\ \alpha^{1/n}, & \text{if } v_n^* \leq x < v_{n+1}^*, \\ 1, & \text{if } x \geq \sup\{v_n^* : n \in N\}. \end{cases}$$

Extremal index

Non-stationarity

Bibliography

- How to check  $\lim_{n \rightarrow \infty} P(M_n \leq v_n) = \alpha$ ?
- By mixing, for some  $k_n \rightarrow \infty$ ,

$$\begin{aligned} P(M_n \leq v_n) &= \left( P(M_{[n/k_n]} \leq v_n) \right)^{k_n} + o(1), \\ &= \exp \left( -k_n P(M_{[n/k_n]} > v_n) \right) + o(1). \end{aligned}$$

- O'Brien (1987) gives conditions for  $k_n$  which allow to write

$$= \exp \left( -n P(X_0 > v_n, M_{[n/k_n]-1} \leq v_n) \right) + o(1).$$

- This extends earlier results of Newell (1964) for  $m$ -dependent sequences and many results for Markov chains (see e.g. Chernick et al. (1991)).

## Managing clusters of big values

- Let us observe that in O'Brien's formula (writing  $r_n$  for  $[n/k_n]$ )

$$P(X_0 > v_n, M_{r_n-1} \leq v_n) = P(M_{r_n-1} \leq v_n) - P(M_{r_n} \leq v_n).$$

- This means that on the one hand

$$P(M_n \leq v_n) = \exp\left(-k_n P(M_{r_n} > v_n)\right) + o(1),$$

while on the other hand

$$\begin{aligned} P(M_n \leq v_n) &= \exp\left(-nP(X_0 > v_n, M_{r_n-1} \leq v_n)\right) + o(1) \\ &= \exp\left(-k_n\left(r_n\left(P(M_{r_n-1} \leq v_n) - P(M_{r_n} \leq v_n)\right)\right)\right) + o(1). \end{aligned}$$

- Hence it must be

$$k_n\left(P(M_{r_n} < v_n) - r_n\left(P(M_{r_n-1} \leq v_n) - P(M_{r_n} \leq v_n)\right)\right) \rightarrow 0.$$

## Managing clusters of big values

### Lemma (J. 1997, also BJMW 2011, Balan & Louichi 2010)

Let  $Z_1, Z_2, \dots$  be strictly stationary random vectors. Set  $T_0 = 0$ ,  $T_k = \sum_{j=1}^k Z_j$ ,  $k \in \mathbb{N}$ . If  $0 \notin U$ , then for every  $n \in \mathbb{N}$  and every  $m \in \mathbb{N}$ ,  $m \leq n$ , the following inequality holds:

$$\begin{aligned} & \left| P(T_n \in U) - n(P(T_{m+1} \in U) - P(T_m \in U)) \right| \\ & \leq 3mP(Z_1 \neq 0) + 2 \sum_{\substack{1 \leq i < j \leq n \\ j-i > m}} P(Z_i \neq 0, Z_j \neq 0). \end{aligned}$$

Set  $n = r_n$ ,  $Z_k = I\{X_k > v_n\}$ ,  $U = (0, +\infty)$ , to get

$$\begin{aligned} & \left| P(M_{r_n} > v_n) - r_n(P(M_{m+1} > v_n) - P(M_m > v_n)) \right| \\ & = \left| P(M_{r_n} > v_n) - r_n(P(X_0 > v_n, M_m \leq v_n)) \right| \\ & \leq 3mP(X_1 > v_n) + 2 \sum_{\substack{1 \leq i < j \leq n \\ j-i > m}} P(X_i > v_n, X_j > v_n). \end{aligned}$$

### Corollary

If  $k_n \rightarrow \infty$  and  $m_n$  are such that

$$\begin{aligned} \lim_{n \rightarrow \infty} k_n m_n P(X_1 > v_n) &= 0, \\ \lim_{n \rightarrow \infty} k_n \sum_{\substack{1 \leq i < j \leq [n/k_n] \\ j-i > m_n}} P(X_i > v_n, X_j > v_n) &= 0, \end{aligned}$$

(plus mixing into  $k_n$  blocks) then

$$P(M_n \leq v_n) = \exp\left(-n P(X_0 > v_n, M_{m_n} \leq v_n)\right) + o(1).$$

## Managing clusters of big values

### Corollary

If  $k_n \rightarrow \infty$  is such that

$$P(M_n \leq v_n) = \left( P(M_{[n/k_n]} \leq v_n) \right)^{k_n} + o(1),$$

$$\begin{aligned} \lim_{n \rightarrow \infty} k_n P(X_1 > v_n) &= 0, \\ \lim_{m \rightarrow \infty} \limsup_{n \rightarrow \infty} k_n \sum_{\substack{1 \leq i < j \leq [n/k_n] \\ j-i > m}} P(X_i > v_n, X_j > v_n) &= 0, \end{aligned}$$

if for each  $m \in \mathbb{N}$  there exists

$$\lim_{n \rightarrow \infty} n P(X_0 > v_n, M_m \leq v_n) = \beta(m),$$

then

$$\lim_{n \rightarrow \infty} P(M_n \leq v_n) = \exp \left( - \lim_{m \rightarrow \infty} \beta(m) \right).$$

## Extremal index due to Leadbetter(1983), also Loynes(1965), O'Brien (1974)

- The extremal index of a stationary sequence  $\{X_j\}$  is a number  $\theta \in (0, 1)$ , such that for all  $\tau > 0$ ,

$$(*) \quad P(M_n \leq u_n(\tau)) \rightarrow e^{-\theta\tau}$$

whenever

$$(**) \quad nP(X_1 > u_n(\tau)) \rightarrow \tau.$$

- Let  $\{\widehat{X}_j\}$  be the sequence “associated” to  $\{X_n\}$ , i.e.  $\widehat{X}_j$ 's are i.i.d. with the same marginal distributions as  $X_j$ :  $\mathcal{L}(\widehat{X}_j) = \mathcal{L}(X_j)$ . Then (\*\*) means  $P(\widehat{M}_n \leq u_n(\tau)) \rightarrow e^{-\tau}$  and (\*) and (\*\*) imply

$$P(M_n \leq u_n) - P(\widehat{M}_n \leq u_n)^\theta \rightarrow 0,$$

at least for sequences  $u_n = u_n(\tau)$  defined by (\*\*).

## Extremal index due to Leadbetter

In fact, Leadbetter (1983) proved that if  $\theta > 0$  then the relation

$$P(M_n \leq u_n) - P(\widehat{M}_n \leq u_n)^\theta \rightarrow 0,$$

holds for **all** sequences  $\{u_n\}$ . Hence  $G(x) = F^\theta(x)$  is a **phantom distribution function** for  $\{X_j\}$ .

### Theorem

Let  $\{X_j\}$  be a stationary sequence. Then  $\{X_j\}$  has the extremal index  $\theta > 0$  if and only if there exists a sequence  $\{v_n\}$  such that Condition  $B_\infty(v_n)$  holds and for some  $\alpha, \widehat{\alpha} \in (0, 1)$

$$\begin{aligned} P(M_n \leq v_n) &\rightarrow \alpha, \\ nP(X_1 > v_n) &\rightarrow -\log \widehat{\alpha}. \end{aligned}$$

In such a case

$$\theta = \frac{\log \alpha}{\log \widehat{\alpha}}.$$

## A standard example

- Let  $Y_1, Y_2, \dots$  be an i.i.d. sequence with regular distribution function  $F$ . Define

$$X_j = Y_j \vee Y_{j+1}, \quad j \in \mathbb{N}.$$

- Then  $\{X_j\}$  is a stationary and 1-dependent sequence with extremal index  $\theta = 1/2$ .
- This is because

$$\begin{aligned} P(\max_{1 \leq j \leq n} X_j \leq v_n) &= P(\max_{1 \leq j \leq n+1} Y_j \leq v_n) \\ &= F(v_n)^{n+1} = \exp\left(- (n+1)(1 - F(v_n))\right) + o(1), \end{aligned}$$

while

$$nP(X_1 > v_n) \sim 2nP(Y_1 > v_n) = 2n(1 - F(v_n)).$$

- A simple task: given a number  $\theta \in (0, 1)$  find a stationary sequence with the extremal index  $\theta$ .

## A model for order statistics

- Let  $\beta_1, \beta_2, \dots, \beta_r \geq 0$  be such that  $\sum_{q=1}^r \beta_q = 1$ , and let  $G$  be a (regular) distribution function.
- For each  $1 \leq q \leq r$ , let  $\{\tilde{Y}_{qj}\}_{j \in \mathbb{N}}$  be independent, identically distributed with

$$\tilde{Y}_{qj} \sim G^{\beta_q}.$$

- Let sequences  $\{\tilde{Y}_{1j}\}_{j \in \mathbb{N}}, \{\tilde{Y}_{2j}\}_{j \in \mathbb{N}}, \dots, \{\tilde{Y}_{rj}\}_{j \in \mathbb{N}}$  be mutually independent.
- Define a new,  $(r - 1)$ -dependent sequence:

$$\begin{aligned} \tilde{X}_j &= \tilde{Y}_{1j} \\ &\vee (\tilde{Y}_{2j} \vee \tilde{Y}_{2,j+1}) \\ &\vee (\tilde{Y}_{3j} \vee \tilde{Y}_{3,j+1} \vee \tilde{Y}_{3,j+2}) \\ &\vdots \\ &\vee (\tilde{Y}_{rj} \vee \tilde{Y}_{r,j+1} \vee \dots \vee \tilde{Y}_{r,j+r-1}). \end{aligned}$$

- Let  $\{X_j\}_{j \in \mathbb{N}}$  be an **arbitrary** sequence of random variables. Define as before  $M_n = \max_{1 \leq j \leq n} X_j$ .
- Suppose one can find a sequence  $\{\tilde{X}_j\}$  of **independent** random variables such that

$$\sup_{x \in \mathbb{R}^1} \left| P(M_n \leq x) - P(\tilde{M}_n \leq x) \right| \longrightarrow 0, \text{ as } n \rightarrow \infty,$$

where  $\tilde{M}_n$  is the  $n$ -th partial maximum of  $\tilde{X}_j$ 's.

- Then  $\{\tilde{X}_j\}$  is said to provide an **asymptotic independent representation** (a.i.r.) for maxima of  $\{X_j\}_{j \in \mathbb{N}}$ .

## Asymptotic Independent Representation for Maxima

- We suggest studying the whole path

$$\mathbb{R}^+ \ni t \mapsto P(M_{[nt]} \leq v_n)$$

and its limit behavior.

- **The idea:** Assume that

$$P(M_{[nt]} \leq v_n) \longrightarrow \alpha_t, \text{ as } n \rightarrow \infty, t \in \mathbb{Q},$$

for some dense subset  $\mathbb{Q} \subset \mathbb{R}^+$  and we **recover an a.i.r.** from the limiting function  $\alpha_t$ , provided the latter is of a special form.

- Note that  $\alpha_t$  is non-increasing and can be **regularized** to the right-continuous function

$$\tilde{\alpha}_t = \sup_{\mathbb{Q} \ni u > t} \alpha_u,$$

for which  $P(M_{[nt]} \leq v_n) \longrightarrow \tilde{\alpha}_t$  at every point of continuity.

## Asymptotic Independent Representation for Maxima

### Theorem, J. (1993)

Assume there is a sequence  $\{v_n\}$  such that for some dense subset  $\mathbb{Q} \subset \mathbb{R}^+ = (0, +\infty)$

$$P(M_{[nt]} \leq v_n) \longrightarrow \alpha_t, \text{ as } n \rightarrow \infty, t \in \mathbb{Q},$$

where the limiting function  $\alpha_t$  possesses the following properties:

$$\alpha_t > 0, t \in \mathbb{Q}$$

$$\sup_{t \in \mathbb{Q}} \alpha_t = 1,$$

$$\inf_{t \in \mathbb{Q}} \alpha_t = 0.$$

Then  $\{X_k\}$  admits an asymptotic independent representation for maxima if, and only if, the function  $g_\alpha = \log \circ \tilde{\alpha} \circ \exp$  is **concave**.
